PLANNING AND CONTROLLING THE ACQUISITION COSTS OF AIR FORCE INFORMATION SYSTEMS

THESIS

Presented to the Faculty of the School of Systems and Logistics of the Air Force Institute of Technology

Air University

In Partial Fulfillment of the
Requirements for the Degree of
Master of Science in Information Resource Management

Thomas J. Falkowski, B.S. Captain, USAF

December 1988

Approved for public release; distribution unlimited

Preface

The purpose of this study was to identify what indicators can be used to more efficiently control the acquisition costs of Air Force information systems. Air Force expenditures on information systems to support their mission are substantial; cash outlays are in the billions of dollars. Because of this, any tools that can be used to improve the planning and control of the acquisition process can be extremely valuable.

Statistical analysis was performed on acquisition data collected from information systems acquired under AFLC's Logistics Management Systems Modernization Program.

Although the limited size of the sample data make the results inconclusive, the methodology presented here provides a means to identify potential indicators.

Throughout my research, data collection, statistical analysis and compilation of this thesis I have depended on the support of many people. My thanks go to my faculty advisor, Lt Col Jeff Phillips, for his encouragement, support and expertise. I would also like to thank my classmate, Capt Al Dunn, whose on going discussions of statistical techniques proved extremely useful in the choice of statistical analysis techniques. My greatest thanks, however, go to my family. To my daughter and to my son who both always seemed to understand when Daddy was "too busy." And finally, my deepest and heartfelt

thanks to my wife Her understanding, patience, and love, provided the impetus for this, and all of my endeavors.

Thomas J. Falkowski

Abstract

The purpose of this study was to identify indicators that can be used to more efficiently control the acquisition costs of Air Force information systems. Statistical analysis was performed on cost data collected Cost/Schedule Status Reports from information systems acquired under Air Force Logistics Command's Logistics Management Systems Modernization Program. Using regression analysis, an initial model was developed that showed the importance of various cost areas on contract performance. The model was then transformed, and reduced, to include only those variables that added significantly to the prediction of contract performance.

Based on the sample analyzed the following cost areas were identified as key indicators of contract performance: Software, Test and Evaluation, Training, and Maintenance. Although the limited size of the sample data make the results inconclusive, the methodology presented here provides a means to identify potential indicators. The goal of this research was not to provide a definitive model that would help program managers to predict contractor performance. Instead, the goal was to establish procedures, or motivation, for program managers to identify key control

variables that can help them to manage their programs more effectively in a time of austere budgets and restricted manpower availability.

PLANNING AND CONTROLLING THE ACQUISITION COSTS OF AIR FORCE INFORMATION SYSTEMS

I. Introduction

Background

An organization's success is dependent, in part, on its ability to plan and control its operations. All major organizational components must have a plan of action, and corresponding control mechanisms, in order for the organization to perform effectively. Fayol, who introduced the idea that a manager plans, organizes, coordinates, and controls, states that a plan of action is one of the most important matters that every business must deal with (8:89). Of equal importance is control. "Control consists of procedures to determine deviations from plans and indicate corrective actions" (3:315).

These planning and control issues are extremely important in dealing with information systems. Management has only recently recognized that information is a resource that must be managed like any other resource within their control (12:3). This information resource is being increasingly managed by automated information systems. In many cases the planning and control must deal not only with

existing systems, but also with the acquisition of new systems that represent a large cost to the organization.

This leads to the issue of how the planning and control of the acquisition of information systems can be improved.

Problem Statement

Planning for the acquisition of information systems is, at best, a complicated process. Many issues must be considered within the organization. In addition to internal considerations, there are many external factors that complicate the process; technology is expanding at a rapid rate. The scope of the acquisition process is too broad to consider all of the issues that impact it. This research will center around budget concerns in an attempt to develop a quantitative model to assist in the controlling of acquisition costs by predicting contractor effectiveness.

Research Objectives

The objectives of this research are (1) to identify what indicators can be used to more efficiently control these costs and (2) to build a prediction model around these indicators.

Investigative Questions

In order to meet the research objectives, I will answer the following investigative questions:

- 1. Which, if any, individual cost variances signal total system cost overruns?
- 2. What is the observed relationship between the individual costs and contract performance.

Justification

Air Force expenditures on information systems to support their mission are substantial. One example of this is the Air Force Logistics Command's (AFLC) \$1.7-billion Logistics Management (LMS) Systems Modernization Program (17:1). The purpose of the LMS Modernization Program is to update the information systems supporting AFLC's worldwide mission.

Scope

The purpose of this study is to examine the observed cost breakdown of information systems acquired under the Logistics Management Systems Modernization Program.

Individual cost areas will be looked at over time in relation to overall program costs. The observed costs will be compared with budgeted costs to determine the corresponding cost variances. The variances will then be examined to determine if specific variances can be used as predictors of overall system cost overruns.

Limitations

Because the population of the study is confined to information systems purchased in support of AFLC the ability of the findings to be generalized to information systems for other major commands may be limited.

II. Literature Review

The concepts of planning and controlling are found throughout the management literature of the past 60 years. It is just recently, however, that the integration of planning and controlling has been addressed. Planning has been described as "a predetermined course of action [that] represents goals and the activities necessary to achieve those goals" (3:300). Controlling, on the other hand, represents "the activity which measures deviations from planned performance and initiates corrective activity" (3:300). The integration of these two functions is seen by some as an important management function of the future (16:39).

This literature review will first address some of the basic concepts of planning and control as individual entities, then together as an integrated function of management. After which, the importance of planning and control relevant to information systems will be discussed. The literature review will end with a brief look at how these issues affect the information systems being procured under the Air Force Logistics Command's Logistic Management Systems Modernization Program.

Planning

Planning is vital to organizations for many reasons.

Davis and Olson give three reasons for organizational planning: to focus the energies and activities of an organization, to settle the differences in objectives among subareas and individuals in the organization, and to lower the uncertainty about what the organization should do (3:300).

Planning occurs at each level of the organization. At the strategic level planning encompasses a broad time horizon, usually more than five years. Strategic planning deals with what function the organization will serve. At the tactical level, the time horizon for planning is shorter, generally between one and five years. Tactical planning deals with the implementation of strategic plans and more specifically the concerns of budgeting for capital expenditures. Operational planning deals with the shortest time horizon, between one and twelve months. At the operational level planners deal with the question of what is the most efficient way to implement the tactical plan and formulation of annual budgets (3:303).

Controlling

Controlling can be looked at as a three-step process consisting of measuring, evaluating, and correcting (9:224).

Measuring consists of determining the progress being made

towards the accomplishment of organizational goals as determined in the planning process. Evaluating deals with analyzing the cause for variations from planned performance and potential corrective action. Correcting is the action taken to remedy an adverse trend (9:224-225). Control is often facilitated through the use of a management planning and control system.

Planning and Control

Bellaschi describes a planning and control system as "a continuous process of establishing plans by one's decision process and information system. Then, through control, adjustments are made, if necessary, to the plans or execution process by again utilizing the decision process and information system" (2:94).

Lorange and Scott Morton describe a more elaborate management control system. Their model is built on the following proposal (10:42):

the fundamental purpose for management control systems is to help management accomplish an organization's objectives by providing a formalized framework for (1) the identification of pertinent control variables, (2) the development of good short-term plans, (3) the recording of the degree of actual fulfillment of short-term plans along the set of control variables, and (4) the diagnosis of deviations.

One of the interesting components of their model is their suggestion that "the linkage between the long-range planning

phase and the control phase is critical for the characterization of the control process" (10:53).

An example of a planning and control system used extensively by the Department of Defense for the acquisition of non-major contracts is the Cost/Schedule Status Report (C/SSR). Cost/schedule status reporting was developed to manage acquisition programs that were considered non-major, and therefore not covered by the DoD Cost Schedule Control Systems Criteria requirements. For DoD purposes, a non-major contract is a development contract under \$25 million, or a production contract under \$100 million (4:1-1).

AFLC Pamphlet 173-2, Cost/Schedule Management of Non-Major Contracts, lists the following purposes of the C/SSR (4:2-4):

- (a) A clear description of the contract cost and schedule status at a given point in time.
- (b) Early indicators of contract cost and schedule problems.
- (c) Quantification, in the form of cost and schedule variances, of the problems and accomplishments being experiences.
- (d) Identification of those WBS elements which are responsible for cost and schedule problems.
- (e) Analysis of the impact if the individual problems on the contract.
- (f) Trend information which can be used to estimate contract final costs.

From this list it may seem at first that C/SSR is just a controlling mechanism and not a part of the planning process. However, the establishment of a Work Breakdown Structure, the original cost estimates, and the

reprogramming that results due to variances link C/SSR to the planning process.

Planning and Control: Information Systems

Beyond the planning and control issues there are also issues that are specific to developing an information systems plan. Above all else, when planning for information systems it is vital that the information systems plan be compatible with, and based on the overall organizational plan (3:446). With the organization's strategic plan in mind, there are four major sections in developing an information systems plan (3:447).

- Information System goals, objectives, and architecture.
- 2. Inventory of current capabilities.
- 3. Forecast of developments affecting the plan.
- 4. The specific plan.

Once a specific information systems plan has been developed, the organization must deal with the management of the procurement process.

Polis lists the following as the ingredients of successful management (14:72):

a thorough understanding of the work to be done; a good contract, technically and managerially; strong technical monitoring of the product; and close monitoring of contractual terms and conditions.

Underlying Polis' recommendations is a theme that was present in much of the literature that dealt with planning of information systems: The idea that the planning for, and

implementation of information systems took a consolidated effort from a cross section of the entire organization (15:52)(14:173)(3:447).

Planning and Control: AFLC LMS Modernization Program

Many of the planning and controlling concepts and information systems specific issues can be seen in the Air Force Systems Command's Logistics Management Systems Modernization Program. The modernization program is an effort to upgrade the command's aging and obsolete computer systems (13:1). Prior to the LMS Modernization Program "Management Information Systems (MIS) developments in AFLC had been done by the major functional organization. . . . There was no standardized, central management of overall MIS acquisition" (13:2). The LMS Modernization Program brought information systems planning more in line with the Command's overall strategic plan and provided the necessary planning and controlling mechanisms to manage the acquisition of the new information systems. It is the data generated from the systems acquired under this modernization program that this research will be conducted on.

III. Methodology

Population

The population for this study is the cost data for information systems being acquired under the AFLC Logistics Management Systems Modernization Program which use cost reporting techniques.

Sample

The sample consists of a census of all available cost data through January 1988.

Definition of Variables

The following variable definitions come from the Standard Work Breakdown Structure (WBS) and Dictionary for Acquisition of Logistics Management Systems Modernization Programs (4:6-17). The variables coincide with the second level of the Work Breakdown structure.

<u>Management (MGMT)</u>. This includes control throughout the five phases of program acquisition. These five phases are conceptual, definition, development, test, and operation.

System Engineering (SYEN). The system engineering element refers to the technical and management efforts of directing and controlling a totally integrated engineering

effort of a system program. This element encompasses the systems engineering effort to define the system and the integrated planning and control of the technical program efforts of design engineering, logistics engineering, specialty engineering, production engineering, and integrated test planning.

Hardware (HARD). Hardware refers to a machine or group of interconnected machines consisting of input, storage, computing, control, and output devices which use electronic circuitry in the main computing element to automatically perform arithmetic and/or logical operations by means of internally stored or externally controlled program instructions.

Software (SOFT). Software refers to those program and routines consisting of a deck of punch cards, magnetic or paper tapes, read-only memory (ROM) units (plug in type) or other physical medium containing a sequence of instructions and data in a form suitable for insertion into the computer and used to direct the computer to perform a desired operation or sequence of operations.

Communications (COMM). The communications network refers to that equipment used to receive and transmit messages of data from a host computer to another computer or from one person or place to another. This equipment includes transmitter, receiver, terminal equipment, internal

facility trunking, modem, cryptographic equipment, power supply, and interface software equipment.

<u>Facilities (FAC)</u>. This activity includes planning, construction, conversion, power and environmental systems, and site inspections.

Test/Evaluation (TNE). The test and evaluation element refers to the use of prototype, production, or specially fabricated hardware to obtain or validate engineering data on the performance of the electronics system. This element includes the detailed planning, conduct, support, data reduction and reports from such testing.

<u>Data/Documentation (DATA)</u>. This data element refers to all deliverable data as listed on a Contract Data requirements list. This elements includes only such effort that can be reduced or will not be incurred if the data item is eliminated.

Training (TRAN). The training element refers to training services, devices, accessories, aids, equipment, and parts used to facilitate instruction through which personnel will acquire sufficient concepts, skills, and aptitudes to operate and maintain the system with maximum efficiency.

<u>Implementation (IMP)</u>. This activity consists of installing, converting and evaluating hardware and/or software systems.

<u>Maintenance (MAIN)</u>. This activity consists of software maintenance, software update, maintenance transfer, hardware repair, and hardware update.

Additional variable definitions for this research are derived from the Department of Defense Instruction 7000.10,

Contract Cost Performance, Funds Status and Cost/Schedule

Status Reports (7:4).

Budgeted Cost Work Scheduled (BCWS). The value of all work to scheduled to be accomplished as of the reporting cut-off date.

Budgeted Cost Work Performed (BCWP). The value of all work accomplished as of the reporting cut-off date.

Schedule Variance (SV). The difference between the BCWS and BCWP.

Cost Variance (CV). The difference between BCWP and ACWP.

Budget at Completion (BAC). The total of all budgeted costs.

Estimate at Completion (EAC). The actual cost to date plus the latest estimate of cost for the remaining work.

The final variable definition is:

Month. The number of months that have elapsed since the date on which work began on a contract and the reporting cut-off date.

All of the variables listed are interval or better.

Developing the Model

Data Manipulation. The first step in developing the model was to manipulate the data so that it was in a uniform format for all of the observations. Although the contracts required a standard WBS, contractors used different conventions in reporting their data. Most notable of the discrepancies in reporting conventions was the treatment of General and Administrative expenses. In some cases contractors separated out General and Administrative expenses as a separate item, while others reported it as part of the individual cost areas. This was remedied by applying General and Administrative expenses back to individual cost areas based on a ACWP for each area divided by the total ACWP for the entire contract. Other similar reporting discrepancies were handled in the same manner.

Dependent Variable. Once the data was in a uniform format, it was necessary to develop a quantitative measure of contract performance that would be descriptive of contract performance regardless of the size of the contract. The measure used was Contract Performance Factor (CPF). The CPF was determined for each observation by dividing the Estimate at Completion by the Budget at Completion.

Contract Performance Factor:

Estimate at Completion/Budget at Completion

For a contract that is currently scheduled to be completed at the budgeted price, the CPF would be equal to one. If

the contract is scheduled to be completed under the budgeted cost, the CPF would be less than one. If the contract is scheduled to be completed over the budgeted cost, the CPF would be greater than one.

Independent Variables. The independent variables are a measure of the costs of each of the 11 cost areas identified in the standard WBS. The measure used is a weighted cost variance. The weighted cost variance consists of the cost variance multiplied by the percentage of money spent on the specific cost area.

Weighted Cost Variance:

(BCWPXXXX-BCWSXXXX) * (ACWPXXXX/ACWPTOTAL)

Where XXXX is the individual cost area

The weighted cost variance was calculated for each of the 11

cost areas and used as the independent variable for each

respective area.

<u>Initial Model</u>. Once the dependent and independent variables were defined each of the cost areas were included in an initial prediction model.

$$E(Y) = B_0 + B_1X1 + B_2X2 + B_3X3 + B_4X4 + B_5X5 + B_6X6 + B_7X7 + B_8X8 + B_9X9 + B_{10}X10 + B_{11}X11$$

Where:

E(Y) = CPF

X1 = Management

X2 = System Engineering

X3 = Hardware

X4 = Software

X5 = Communication

X6 = Facilities

X7 = Test and Evaluation

X8 = Data

X9 = Training

X10 = Implementation

X11 = Maintenance

Validating and Transforming the Model

After the initial model was defined it was necessary to check the model validity by determining if the model assumptions are met. The assumptions are made about the error, or residuals values, of the model (11:407).

Assumption One: The mean of the probability distribution of error is zero.

Assumption Two: The variance of the probability distribution of the error is constant.

Assumption Three: The probability distribution of the error is normal.

Assumption Four: The errors associated with any two different observation are independent.

These assumptions were initially checked by using a residual analysis and by examining scatter plots of the each independent variable plotted against the dependent variable. Needed corrections were made to the initial model by applying transformations to the model variables when appropriate.

Reducing the Model

The final step was to take the transformed model and reduce it to only those variables that added significantly to the usefulness of the model. (A level of significance of .05 was established as a threshold for eliminating independent variables.) The resulting reduced model was once again checked for compliance with model assumptions.

IV. Findings and Analysis

Model Analysis

In Chapter Three the initial model was defined as $E(Y) = B_0 + B_1X1 + B_2X2 + B_3X3 + B_4X4 + B_5X5 + B_6X6 + B_7X7 + B_8X8 + B_9X9 + B_{10}X10 + B_{11}X11.$

A regression was performed using this model with the SAS Statistical Package. (All statistical procedures were performed using SAS). The results are in Table 1.

From the initial regression it appears that the model is useful in determining the contract performance factor. The coefficient of determination, R², implies that 77.05% of the variation in CPF can be accounted for by the model. The results of the global F test show that the observed significance level, or p-value, is .0001 indicating a strong probability that at least one of the model coefficients is nonzero, and therefore useful in predicting the CPF.

<u>Independent Variables</u>

Looking at the independent variables individually, however, it appears that some of the variables are not useful in determining CPF. P-values range from less than .0001 for Software and Communication, to .8640 for Facilities. Further analysis is required to determine which variables to eliminate from the model.

Table I: Regression Results -- Initial Model

Initial Transformations

An examination of the residual plots and scatter plots for each of the independent variables proved inconclusive at this point in the data analysis (Appendix A). Clearly random residual plots were not obtained due to the limited number of observations available. Because of the constraint

imposed by the limited amount of data that has been reported on the contracts to date, the residual plots were examined to see if any patterns would clearly indicate violations of the model assumptions. The scatter plots were also examined to look for clues to possible transformations that could improve the model. Ultimately, each independent variable was individually transformed using each of the following transformations:

$$x = 1/x$$
 $x = x^2$ $x = x^3$ $x = \log x$ $x = x^{1/2}$

where x = an independent variable

The results for some of these transformations were undefined due to the value of x being equal to zero in some instances. In other cases, where the transformation resulted in real values, the transformed variables failed to show any improvement in the model. In only one case did the transformation process achieve positive results: the transformation of the independent variable Software.

Software. The independent variable software had a level of significance in the initial regression of .0001. In addition to this an examination of the scatter plot and residual plot indicated that a transformation might be appropriate. After several different transformations were tried, squaring the independent variable software was chosen as the most effective. A new regression was run using a single independent variable: the weighted cost variance of software costs squared (SOFTS). The results are in Table 2.

Table II: Software Regression Results

The new regression run with single transformed variable, software squared, has a coefficient of determination, R², of 77.17%. This is slightly higher than the R² value for the initial regression that had included all of the variables. An examination of the scatter plot, (see Appendix B), shows that the relationship between CPF and the transformed independent variable Software approximates a linear relation. Examining the Residual Plots shows an improvement over those plotted from the initial regression that contained all of the variables. Because of the relatively small number of observations on which the analysis is based,

it is difficult to determine with certainty whether the plots indicate that the model assumptions have been met.

Transformed Model

A new regression was run with all of the original independent variables. This time, however, the software variable was transformed to Software Squared. The results are found in Table 3.

The results of the transformed model show a slight improvement over the original. The new requare value indicates that now 82.63% of the variation of CPF can be attributed to the independent variables.

Reducing the Model

The discussion on the independent variables stated that some of the variables should be removed from the model. The transformed model was screened using the SAS STEPWISE procedure. The summary of the results are found in Table 4, and the complete procedure is found in Appendix C.

Table IV: Summary of STEPWISE PROCEDURE

Although this was a marked improvement from the eleven independent variable in the original model, the model that the STEPWISE procedure suggested, had a Mallow's Cp value of 2.9816. For a model with six parameters, this value indicates a great deal of bias. Therefore, the analysis was continued in search for a better model. In order to do this, all possible subset models were considered using the SAS RSQUARE procedure. The results are presented in Appendix D.

In addition to providing the rsquare value, The RSQUARE procedure also reports the value of Mallow's Cp for all possible models. The value of Mallow's Cp measures the

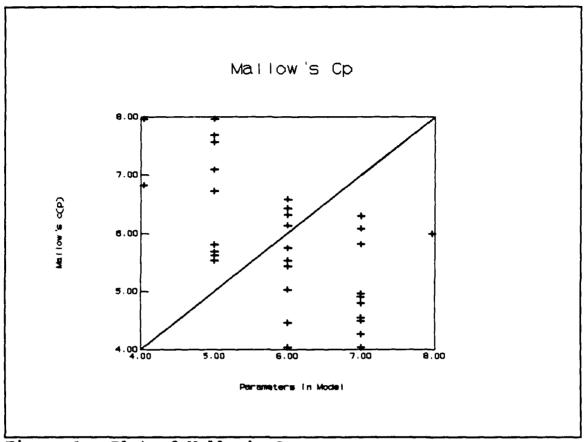

Figure 1: Plot of Mallow's Cp

precision of the prediction model by taking into account the bias of the model. Values of Cp that are close to the number of parameters in the model have less bias than models that have a Mallow's Cp value that varies significantly from the Cp value. Graphically, these values lie close to the line in Figure 1. Based on the results of the RSQUARE procedure, two models were selected for further consideration. These models were selected by looking at both their R², and the Cp values.

The first of these models contains five independent variables: Software Squared, Facilities, Test and

Evaluation, Training, and Maintenance. The R² for this model is .8128 and the Cp is 5.747. The second model contains four independent variables: Software Squared, Test and Evaluation, Training, and Maintenance. The R² for this model is .8086 and the Cp is 5.5302. The complete regression results of each of these models are found in Appendices E and F.

The first step in distinguishing between these two models is by comparing their adjusted rsquare values. five variable model has an adjusted rsquare of .8011. four variable model has an adjusted rsquare of .7992. seems to indicate that the five variable model is better able to predict the CPF. Looking at the variables individually, the five variable model, contains a variable with a p-value of .1849 (Facilities). This is above the threshold established in the methodology for eliminating a variable. Before eliminating the Facilities variable, a regression on the five variable model was performed and a partial f-test comparing it to the 4 variable model. The results are in Appendix G. The results (F-value=1.788 and corresponding p-value of .1849) indicate that at a level of alpha = .05 the null hypothesis that the beta value for Facilities is zero cannot be rejected. Based on this Ftest, and the p-value, the Facilities variable was eliminated from the model and the four variable model was chosen.

The following is the resulting model:

CPF =

1.04644+.00000184SOFTS-.00021672TNE-.0158107TRAN-.134643MAIN

The residuals were once again plotted to check for model assumptions and look for possible transformations (See Appendix H). The residual plots again seemed inconclusive as to the satisfying of model assumptions due to the limited data availability. Three transformations were performed to see if the model could be improved:

1/CPF LogCPF CPF^{1/2}

In each instance, there was a decrease in the rsquare value and no noticeable improvement in the random nature of the residual plots. Therefore the four variable model was not transformed.

Model Significance

The level of significance for the variables range from .0001 to .0230. The individual p-values are as follows:

Software Squared .0001

Test and Evaluation .0230

Training .0084

Maintenance .0011

When looking at the significance of the model it is important to point out that the value of the model is not found in the exact Beta values of the model parameters. Instead, it is important to look at which variables were included in the model.

Research Objectives

In Chapter One, the following research objectives were established:

(1) to identify what indicators can be used to more efficiently control of information systems costs and (2) to build a prediction model around these indicators.

In response to the first objective, the weighted cost variance of Software, Test and Evaluation, Training, and Maintenance are key indicators of overall contract performance.

As for the second research objective, the prediction model for the Contract Performance Factor can be used for predicting contract cost performance, but that is not where the real worth of the model lies. Instead, by looking at the model, acquisition managers can focus on costs associated with the key variables the model identifies in order to better control the acquisition of information systems.

V. Conclusion and Recommendations

Practical Implications

When looking at the practical implications of this research it is important to realize that the specific model developed is limited in its ability to be generalized to other populations. However, there are a number of things that can be taken from this research and universally applied. One of the important steps in developing a methodology was to come up with ratio type performance indicators. The dollar value of the contracts in the analysis differed significantly. Therefore it was necessary to have a measure that meant the same thing regardless of the size of the contract. The Contract Performance factor did just that. Regardless of the size of the contract, the Contract Performance Factor provides a measure that readily identifies the performance of a contractor.

The next item of importance in the methodology was finding a way to measure the importance of each cost area taking into consideration both the contract size, and the amount of money allocated to the cost area. The weighted cost variance accomplished both these things. In addition to developing ratio type measures for the model variables, identifying key variables is also a vital issue.

The management of the acquisition of information systems is a complex task. The idea of identifying key variables to focus on when monitoring contractor progress can significantly improve a program manager's effectiveness. It is interesting to note that the indicators that were identified in this analysis were all intangible in nature. The variables that were eliminated were either tangible things, like hardware or facilities, or they were intangible areas that have been in existence for quite some time, for example management and systems engineering. This might indicate that as experience is gained in an area it has less impact on contract performance. Conversely, the performance in areas that are still relatively new, or difficult to quantify, have a greater impact on contractor performance.

Policy Implications

The goal of this research is not to provide a definitive model that will help program managers to predict contractor performance. Instead, the goal is to establish procedures, or motivation, for program managers to identify key control variables that will help them to manage their programs more effectively in a time of austere budgets and restricted manpower availability.

Recommendations

At the time this research began, the cost data for programs under the LMS were just beginning to be compiled. Some contractors were having difficulty in complying with the C/SSR reporting requirements and other contracts were not yet on cost type contracts. Because of this, the available data was limited, and some if it was unusable due to unreliability. It is recommended that the data be recompiled and the methodology repeated with a larger data base. The availability of a larger sample would be extremely useful in improving the reliability of the model and the determination of the variables to include.

An analysis of the types of variables that are selected for inclusion in future models would also be beneficial. The answers to questions like: Are intangible cost areas more significant in determining contractor performance? or does experience in a specific cost area lessen its impact on contract performance? Finding the answer to this type of questions can improve the efficiency and effectiveness of program managers.

<u>Vita</u>

Captain Thomas J. Falkowski was born on He graduated School 1975. He then attended the School of Management at Boston College in Chestnut Hill, Massachusetts. He received a Bachelor of Science degree in Finance from Boston College in May of 1979. He enlisted in the USAF in December of 1982. After completion of training, he served as a weather specialist at Detachment 11, 7th Weather Squadron, Coleman Barracks, West Germany. In July 1984, he enter OTS at Lackland AFB TX and received his commission in October 1984. After completion of Administrative Officers' School at Keesler AFB MS, he was assigned to the 9th Strategic Reconnaissance Wing, Beale AFB California. While at Beale AFB, he served as the Executive Officer, and then, as the Squadron Section Commander for the 9th Civil Engineering Squadron. He attended Squadron Officer School at Maxwell AFB AL prior to entering the School of Systems and Logistics, Air Force Institute of Technology, in June 1987.

TON THE

The purpose of this study was to identify indicators that can be used to more efficiently control the acquisition costs of Air Force information systems. Statistical analysis was performed on cost data collected from Cost/Schedule Status Reports from information systems acquired under Air Force Logistics Command's Logistics Management Systems Modernization Program. Using regression analysis, an initial model was developed that showed the significance of various cost areas on contract performance. The model was then transformed and reduced, to include only those variables that added significantly to the prediction of contract performance.

Based on the sample analyzed the following cost areas were identified as key indicators of contract performance: Software, Test and Evaluation, Training, and Maintenance. Although the limited size of the sample data make the results inconclusive, the methodology presented here provides a means to identify potential indicators. The goal of this research was not to provide a definitive model that would help program managers to predict contractor performance. Instead, the goal was to establish procedures or motivation, for program managers to identify key control variables that can help them to manage their programs more efficiently in a time of austere budgets and restricted manpower availability.
